Abstract

This workshop paper aims at briefly presenting the authors' previous experience in the field of sociotechnical design of mHealth applications and at illustrating the opportunity in joining forces of multidisciplinary researchers, domain experts, and practitioners for improving the field.

Author Keywords

Chronic Diseases; mHealth; Mobile Devices; Personal Health Records; Patient Engagement; Patient Empowerment; Sociotechnical Design.

ACM Classification Keywords

mHealth for Chronic Diseases

mHealth is aimed at providing remote health care by the use of mobile technology and devices. In [1] a systematic review on scientific literature about the management of chronic diseases has been presented and discussed. In particular, the review included the analysis of 107 papers and compared usability, feasibility, and acceptability of mobile tools and platform used. From the results, it emerged that the most commonly used mobile technology (40.2%), was still Short Message Service (SMS). Particularly, about

the practice of mHealth for anticoagulant therapy management (that is the specific application domain we consider in our past research), several studies have been carried out in the past years but none of them ended in actual implementation into practice (e.g., [2], [3], [4]).

The scientific literature available today strongly proves how the use of electronic management of health records can be of advantage both for patients and for healthcare practitioners, especially with what concerns a better management of National Health Systems (e.g., [5], [6], [7]).

By analyzing the existing literature and the outcomes of our previous research work we can state that there are two main advantages in implementing mHealth solutions for chronic diseases: the first is more related to its social impact and is the increasement of patients' awareness in their health condition. The second one is related to a reduction of costs for the National Health Systems. As a significant example, Javitt et al [8] shows that the adoption of mHealth technology for diabetes monitoring can lead to a significant reduction in medical expenditures, estimated in about $3,000 per person per year.

At European level, the importance of mHealth and eHealth in general is largely recognized by the eHealth Action Plan 2012-2020 - Innovative healthcare for the 21st century [9]. In fact, in this period, until 2020, research and innovation will be supported under the programme "Health, demographic change and wellbeing" of Horizon 2020. Specifically, the research that will be funded has to be focused on (i) the exploitation of ICT and computer science for digital, personal, and predictive medicine, (ii) new tools and methods for improving diagnostics and decision making processes; (iii) the study of new mobile technologies and applications and of digital media in general to integrate existing healthcare and social care systems; (iv) the design of eHealth systems and services that enable a stronger user empowerment and involvement to move towards a more patient-centric healthcare system.

The MANTRA Project Experience
In 2013, two of the authors were involved in MANTRA (Mobile ANticoagulant TheRApy), a Leverlhume Trust funded project developed at University of West London, aimed at introducing mobile devices in anticoagulant therapy practice to improve the quality of life of patients. By the evaluation of the MANTRA Project, we developed a general approach to mHealth in the remote management of chronic diseases by supporting the communication among patients and healthcare practitioners. Patients usually have to make frequent visits to surgeries to meet nurses for the tests, and General Practitioners (GPs) for receiving drug prescriptions. The main goal of MANTRA was to study feasibility and acceptability of the introduction of mobile technology in the management of anticoagulant therapy involving both patients and health practitioners in their design. The MANTRA Project design, implementation and evaluation is reported as a proof of concept carried out in London [10] and also in Venezuela, by exploring a specific case of mHealth in rural areas [11]. In particular, from the London-based case, the distinct characteristics of the NHS as one of the world's largest publicly funded health services, posed a number of sociotechnical challenges. We may classify into four main classes and generalize them

from anticoagulant therapy to chronic diseases at large: 1) *Flexibility*: drugs prescription is subject to requirements the local national health system. 2) *Accessibility*: most of the patients who follow therapies for chronic diseases are elderly. 3) *Data visualization*: it is fundamental for the user to access history of therapy to learn from previous behavior and to monitor improvement or retrogression. 4) *Safety*: this is one of the most important characteristics that a mHealth application should have to be considered as appropriate for a clinical use.

The field of mHealth for chronic diseases management offers the opportunity to capitalize on a wide scientific literature production to improve the current medical practice, both in terms of doctor-patient communication and patient engagement/empowerment.

Significance to the Workshop
To participate to the workshop "Mobile Healthcare for the Self-Management of Chronic Diseases and the Empowerment of Patients" at MobileHCI 2016, will allow us to share with other scientists, domain experts, patients associations, and practitioners the challenges that we identified in our previous experience in the field. Moreover, this workshop will be an important occasion to eventually plan prospective future collaborations on the aspects of mHealth that strongly need further investigation:

- Method, techniques, technologies, and design approaches for improving the level of patients' engagement in therapy management in order to contribute to a higher efficacy and effectiveness of the cure and to a higher patients' satisfaction.

- Research or Industry case studies focused on improving patients' quality of life supporting tools for self-monitoring and self-management of their chronic diseases.

- Sociotechnical studies on methods for improving the quality of doctor-patient relationship enabling the construction of direct and fast communication channels focusing on data and avoiding time wasting.
